THE JAMES WEBB SPACE TELESCOPE

NASA's James Webb Space Telescope is a true technological marvel. The largest and most complex space telescope ever built, Webb will be able to gather light that has been traveling for 13.5 billion years, almost since the beginning of the universe. In effect, Webb is a time machine, allowing us to peer at the first galaxies to form after the Big Bang. Because it gathers infrared light, it will see right through the giant clouds of dust that block the view of most other telescopes. Webb will be 100 times more powerful than the Hubble Space Telescope. Most notably, once it unfolds its 21-foot-wide (6.5-meter-wide) set of segmented mirrors, Webb will be powerful enough to search for water vapor in the atmospheres of planets orbiting other stars. It will open a new window on these exoplanets, observing them in wavelengths of light at which they have never been seen before and helping us gain new insights about their nature. Webb will help us understand how galaxies evolve over billions of years into grand spirals, like our own Milky Way, search for signs of habitability on distant planets, and penetrate into the hearts of dust-shrouded stellar nurseries. The observatory is expected to launch in 2021.

Webb is an international collaboration among NASA, the European Space Agency, and the Canadian Space Agency.
